Pulmonary Clinic Flow Simulation Model Review

Denise White Craig Froehle Amy Chima Robin Hamilton Division of Health Policy & Clinical Effectiveness Updated: 05/27/10

change the outcome^{*}

Purpose & Background

- In order to improve patient flow through clinic, we need to understand the impact of the scheduling template as well as the interrelationships of all of the process steps, variability of patient needs, and the availability of appropriate staff at each step in the process.
- "<u>Simulation</u> is the process of designing and creating a computerized mathematical model of a real or proposed system for the purpose of conducting numerical experiments to give us a better understanding of the behavior of that system for a given set of conditions."
- Because of the difficulty to test different options on the system itself, a simulation model is a perfect tool for providing insight into what changes need to be made, and we can test changes to see the impact to clinic flow in a computer "laboratory" setting.

change the outcome[®]

Simulation Model Design

This model simulates the clinic flow of the Pulmonary Department (located at the base) from patient arrival to service completion that may include pulmonary testing procedures and the services of multiple providers in order to find improvements in flow that results favorable service level measures for the patients while maintaining or improving clinical efficiency.

AIM

• To examine and test the effect of operational changes on clinical measures.

Potential What-If Scenarios/Recommendations

- How should exam rooms be allocated to doctors in a clinic setting?
- Are the resource allocations sufficient?
- Can scheduling or flow modifications be made to improve clinic measures?
- Can variance reduction improve performance?

Outcome Performance Measures

- Patient Touch Time/ Wait Time Measures
- Resource Utilization
- Clinic Duration

Model Snapshot

Patients arrive based on scheduling templates of physicians with appointment type determined by template.

Flow scenarios (by appt type) assigned based on historical data.

Patient Results

Understanding Patient Flow

Some principles of patient flow:

- Time is a finite and costly resource
- Variability is only bad when it's unanticipated
- System-level performance depends on each individual's actions; everything's connected
- Waiting is minimized when schedule matches actual work

Variability in Consultation Durations

60-minute appointments

Variability in Consultation Durations

PDSA: Reduce Activity Duration Uncertainty

Hold physician consultation times to scheduled durations

- If scheduled for 30 minutes, then the physician's meeting with patient ends at 30 minutes (if not before)
- Depends on physician and patient/appointment type

Hold non-physician activity times to 150% of historical averages

Methods

- Data collection
 - Manual timestamp entry into EPIC
 - 1 clinic met data integrity threshold
 - Extracted empirical time distributions
- Simulation
 - Built simulation model of that specific clinic
 - 150 replications of a clinic session per scenario
 - Used same patient set each time (var. reduction)

change the outcome[®]

Conclusions

Methodological

- Simulation allows for rapid prototyping of potentially disruptive changes and improvement activity
- Validity of results depends on input data

Operational

- Accurate scheduling + conscientious behavior can lead to large improvement on key metrics
- Managerial decisions influence flow with the potential for synergy
- Improvements rely on actions of all providers
