

Pectus Excavatum

FAST FACTS

**1 in
300 – 400**

prevalence of pectus excavatum

80:20

male to female ratio of pectus excavatum patients

15.2 years

mean age at surgery

40%

family history of pectus

10 – 20%

of patients with pectus have associated connective tissue disease

Pectus excavatum (PE) is a deformity of the cartilaginous portion of the anterior ribs where they attach, causing the sternum to be pushed inward and resulting in a caved-in or sunken appearance. The most common chest wall deformity, PE is 3 – 5 times more likely to occur in males than females.

Patients may present either at or shortly after birth, or during the prepubertal growth spurt. Concavity of the sternum may result in compression of the heart or cause restrictive lung disease. Despite common cardiac compression, younger children and teens may display minimal symptoms due to the flexibility of the chest wall and enhanced compensatory mechanisms of youth.

ASSESSMENT

Perform a standard history and physical examination with probing questions around cardiopulmonary symptoms. Look for an indentation of the chest wall. Assess the back for associated scoliosis. Assess for hypermobility and other signs of Ehlers-Danlos or Marfan's disease. Question patient regarding psychosocial issues including disturbed body image, depression, and/or social isolation.

HPE RED FLAGS

- Chest pain
- Shortness of breath, at rest or with exertion
- Irregular heartbeat, heart murmur
- Exercise intolerance
- Fatigue
- Abnormal spinal curvature
- Generalized hypermobility
- Other symptoms of Ehlers-Danlos, Marfan's, Noonan, or postural orthostatic tachycardia syndrome

Cardiopulmonary symptoms may progress with age as the chest wall becomes less flexible and the patient's ability to compensate for the fixed pressure on the heart decreases. Significant cardiopulmonary dysfunction associated with PE may increase with age and severity of the defect and can be improved through repair.

WHEN TO REFER

Refer any patient with concerns for a chest wall condition whenever it is identified on clinical evaluation to Cincinnati Children's Chest Wall Center for further evaluation and treatment.

If you would like additional copies of this tool, or would like more information, please contact the Physician Outreach and Engagement team at Cincinnati Children's.

If you have clinical questions about patients with pectus excavatum, email chest-wall-center@cchmc.org

Pectus Excavatum

Inclusion Criteria

- Patient with sunken chest wall

Patient Presents

Standard Workup

Situational History

- Chest pain
- Shortness of breath
- Exercise intolerance
- Fatigue
- Palpitations
- Psychological impact

Family History

- Marfan's syndrome
- Ehlers-Danlos syndrome
- Noonan syndrome
- Postural orthostatic tachycardia syndrome

Physical Exam

- Sunken chest wall
- Irregular heartbeat, heart murmur
- Abnormal spinal curvature
- Generalized hypermobility

HPE RED FLAGS

- Chest pain
- Shortness of breath, at rest or with exertion
- Irregular heartbeat
- Exercise intolerance
- Fatigue
- Abnormal spinal curvature
- Generalized hypermobility
- Other symptoms of Ehlers-Danlos, Marfan's, Noonan, or postural orthostatic tachycardia syndrome

Refer all patients with concern for pectus excavatum to Cincinnati Children's Chest Wall Center for consultation.

At consultation, recommendations for treatment will be made based on age, severity of defect, and symptoms.

Expected management depending on child's age and severity of defect

Age 0 – 6 years

- Reassure
- Annual follow-up

Age 6 – 10 years

- Annual follow-up
- Vacuum bell (non-surgical treatment) — first line therapy
- Surgery (minimally invasive Nuss procedure) — only for severe, symptomatic defects in this age group

Age 11 – 16 years

- Annual follow-up
- Vacuum bell (non-surgical treatment) if milder defect and chest wall remains flexible
- Surgery (minimally invasive Nuss procedure) — most common in this age group

Standard preoperative evaluation for pectus excavatum

Cardiac MRI

- To assess depth of pectus, cardiac compression, anatomy and function

EKG

- To assess heart rhythm

Cardiopulmonary exercise test

- To rule out cardiac or pulmonary limitation to exercise

Pulmonary function test

- To evaluate lung function

For urgent issues, or to speak with the specialist on call 24/7, call the Physician Priority Link at 1-888-636-7997.
